

4.5 ~ 18V, 0.75 ~ 5A, Current Limit Power Switch with Reverse Block

General Description

The ET20170 is a current limit N-Channel MOSFET power switch. It is designed to protect circuitry on the output from transients on the input. It also protects the input from undesired shorts and transients coming from the output.

The current limit magnitude is controlled by an external resistor from ILIMIT to GND. It is fixed 0.73A when ILIMIT is floating. Programmable soft-start time controls the slew rate of the output voltage during the start-up time. It can be controlled by the DV/DT pin setting.

The ET20170 offer a GATE drive signal connected to an external N-Channel MOSFET gate to block current flowing from the output to the input when the IC is disable, power off or thermal shutdown.

Features

- V_{IN} Operating Range: 4.5V to 18V
- Programmable Current Limit and Soft-Start Time
- Short-Circuit Protection
- Typical R_{ON} : 31m Ω From Input to Output Power Path
- Very Low Quiescent Current: 110 μ A (Typ)
- Reverse-Blocking MOSFET Driver
- Over-Current Protection
- Internal Thermal Shutdown Protection
- ESD Human Body Model Protected: All pins $\pm$ 2KV Pass
- Package Information

Part No.	Package	MSL
ET20170	DFN10 (3.0mm $\times$ 3.0mm)	Level 1

Application

- SSD Hard Disk
- PC Cards
- Wireless Modem Data Cards
- USB Power Distribution/USB Protection
- USB 3.1 Power Delivery
- Server PC

ET20170

Pin Configuration

Pin Function

Pin	Name	Description
1	DV/DT	Soft start programming pin. Connect a capacity from DV/DT to GND to set the DV/DT slew rate.
2	EN	This is a dual function control pin. When used as an ENABLE pin and pulled down, it shuts off the internal pass MOSFET and pulls BFET to GND. When pulled high, it enables the device and BFET. As an UVLO pin, it can be used to program different UVLO trip point via external resistor divider.
3,4,5	VCC	Power supply input. Must be closely decoupled to GND pins with a 1uF or greater ceramic capacitor. Connect VCC using a wide PCB trace.
6,7,8	SOURCE	Source of internal power n-channel MOSFET and the output terminal.
9	GATE	Gate pin for external reverse-current block MOSFET.
10	ILIMIT	Current limit programming pin. Program the current limit by connecting a resistor to GND. Floating ILIMIT pin to achieve a 0.73A fixed current limit.
11	GND	Ground pin.

Block Diagram

Operation

ET20170 is an integrated power switch with a low $R_{DS(on)}$ N-Channel MOSFET. When the ET20170 turns on, it can deliver up to 5A continuous current to load. When the device is active, the device only consumes 110uA supply current if no load.

Power Supply Considerations

At least 1μF MLCC capacitor between VCC and GND, close to the device, is recommended. Placing a high-value electrolytic capacitor on the output pin is recommended when the output load is heavy. This precaution reduces power-supply transients that may cause ringing on the input and minimize the input voltage droops. Additionally, bypassing the output with a 10μF MLCC capacitor improves the immunity of the device to short-circuit transients.

Current Limit (ILIMIT)

A sense FET is employed to check for over current conditions. When an over current condition is detected, the device maintains a constant output current and reduces the output voltage accordingly. ET20170 will limit the current until the overload condition is removed or the device begins to thermal cycle.

The current limit can be programmed by an external resistor. It can be approximated with equation below.

$$I_{LIMIT} = 0.7 + 3 \times 10^{-5} \times R_{LIMIT}$$

The ET20170 allows ILIMIT to be floated during operation. The internal fixed current limit threshold is set at 0.73A. The current limit response time is about 20us⁽¹⁾.

Short-Circuit Protection (SCP)

During a transient short circuit event, the current through the device increases very rapidly. The current-limit amplifier cannot respond very quickly to this event due to its limited bandwidth. Therefore, the ET20170 incorporates a fast-trip comparator, which shuts down the pass device very quickly when $I_{OUT} > I_{FASTTRIP}$, and terminates the rapid short-circuit peak current. The trip threshold is set to 50% higher than the programmed overload current limit ($I_{FASTTRIP} = 1.5 \times I_{LIMIT}$). After the transient short-circuit peak current has been terminated by the fast-trip comparator, the current limit amplifier smoothly regulates the output current to I_{LIMIT} .

To prevent safe operating area (SOA) damage during a high input voltage short-circuit protection(SCP) condition, the IC current limit folds back when the power MOSFET VDS voltage is above the typical 11V and the junction temperature is over 100°C.

Soft Start

The soft start time can be set by an external capacity connecting from DV/DT to GND. The soft start time can be calculated with Equation:

$$t_{DVDT} = \frac{VCC}{GAIN} \times (C_{DVDT} + 70pF) / I_{DVDT} = 10^6 \times VCC \times (C_{DVDT} + 70pF)$$

where:

- GAIN=8V
- $I_{DVDT}=125nA$

The dV/dt slew rate is determined by external DVDT capacitor.

Reverse-Blocking MOSFET Driver

The ET20170 has a GATE pin to provide an external N-channel MOSFET gate drive signal for reverse-current protection (RCP).

If GATE pin float, there is no RCP function.

Thermal Protection - Lock-Out

Thermal protection prevents damage to the IC when heavy-overload or short-circuit faults are present for extended periods of time. The ET20170 implements a thermal sensing to monitor the operating junction temperature of the power MOSFET. In an over-current or short-circuit condition, the junction temperature rises due to excessive power dissipation.

Once the die temperature rises to approximately 155°C due to over-current conditions, the internal thermal sense circuitry turns the power switch off, thus preventing the power switch from damage. The chip will restart when re-enable or re-power-on.

Three events can pull down the GATE voltage: VIN below the under-voltage lockout (UVLO), the enable (EN) voltage below the low level threshold, or thermal shutdown. If any of these conditions occur, GATE sinks the current from the gate of the external MOSFET to initiate a fast turn-off.

Note1: Test condition is as $V_{IN}=12V$, $I_{LIMIT}=3.7A$, $T_A=25^{\circ}C$, $C_{OUT}=0\mu F$. Current Limit Response Time is the time difference between I_{OUT} first exceeding I_{LIM} and falling back to I_{LIM} . and falling back to I_{LIMIT} . Short-circuit Response Time is the time difference between I_{OUT} exceeding $I_{FASTrip}$ and falling back to 0A.
