# ET4559 - SIM Card Interface Level Translator With

# **EMI Filter and ESD Protection**

### **General Description**

The ET4559 device is built for interfacing a SIM card with a single low-voltage 1.08V to 1.98V host side interface. The ET4559 contains three 1.62V to 3.6V level translators to convert the data, RST and CLK signals between a SIM card and a host micro controller.

The ET4559 is compliant with all ETSI, IMT-2000 and ISO-7816 SIM/Smart card interface requirements.

### Features

- Supports clock speed up to 10MHz clock
- Compliant with all ETSI, IMT-2000 and ISO-7816 SIM/Smart card interface requirements
- Support SIM card supply voltages with range of 1.62V to 3.6V
- Host micro controller operating voltage range: 1.08V to 1.98V
- Automatic level translation of I/O, RST and CLK between SIM card and host side interface with capacitance isolation
- Incorporates shutdown feature for the SIM card signals according to ISO-7816-3
- Automatic enable and disable through VCCB
- Integrated pull-up and pull-down resistors: no external resistors required
- Integrated EMI filters suppress higher harmonics of digital I/Os
- Integrated 8kV ESD protection according to IEC 61000-4-2, level 4 on all SIM card contact pins
- Level shifting buffers keep ESD stress away from the host (zero-clamping concept)
- Pb-free, Restriction of Hazardous Substances (RoHS) compliant and free of halogen and antimony (Dark Green compliant)
- Part No. and Package

Part No.	Package	MSL
ET4559	FOCSP9 (1.06 mm × 1.06 mm × 0.43 mm; 0.35 mm pitch)	Level 1

### Applications

- Mobile and personal phones
- Wireless modems
- SIM card terminals

**Pin Configuration** 

## **Pin Function**

Pin	Pin No.	Туре	Description
RST_HOST	A1	I	Reset input from host controller.
V <sub>CCA</sub>	A2	Supply	Supply voltage for the host controller side input/output pins (CLK_HOST, RST_HOST, IO_HOST). This pin should be bypassed with a $1\mu$ F ceramic capacitor close to the pin.
RST_SIM	A3	0	Reset output pin for the SIM card.
CLK_HOST	B1	I	Clock input from host controller.
GND	B2	Ground	Ground for the SIM card and host controller. Proper grounding and bypassing are required to meet ESD specifications.
CLK_SIM	B3	0	Clock output pin for the SIM card.
IO_HOST	C1	I/O	Host controller bidirectional data input/output. The host output must be on an open-drain driver.
V <sub>ССВ</sub>	C2	Supply	SIM card supply voltage. When $V_{CCB}$ is below the $V_{CCB}$ disable, the device is disabled. This pin should be bypassed with a $1\mu F$ ceramic capacitor close to the pin.
IO_SIM	C3	I/O	SIM card bidirectional data input/output. The SIM card output must be on an open-drain driver.

### **Block Diagram**

### Operation

The ISO 7816-3 specification specifies the shutdown sequence for the SIM card signals to ensure that the card is properly disabled for power savings. Also during hot swap, the orderly shutdown of these signals helps to avoid any improper write and corruption of data.

When the  $V_{CCB}$  disable,  $V_{CCB_DIS}$ , the shutdown sequence is initiated by powering down the RST\_SIM channel. Once the RST\_SIM channel is powered down, CLK\_SIM and IO\_SIM are powered down sequentially one-by-one. An internal pull-down resistor on the SIM pins is used to pull these channels LOW. The shutdown sequence is completed in a few microseconds.

3

### VCCB enable

The device contains an auto-enable feature. If  $V_{CCB}$  rises above  $V_{CCB\_EN}$ , the level translator logic is enabled automatically. As soon as  $V_{CCB}$  drops below the  $V_{CCB\_DIS}$ , the SIM card side drivers and the level translator logic is disabled. Host side IO pin is configured as input with a 4.3k $\Omega$  resistor pulled up to  $V_{CCA}$ .

When the V<sub>CCB</sub> drops below V<sub>CCB</sub> disable voltage but is still higher than a MOS threshold (e.g. 0.8V) the pull-down NMOS in the one-directional drive will be off and NMOS controlled by CTL will be on, and the 400 $\Omega$  resistor will keep the card side CLK/RST/IO low. Additionally the CLK/RST pins on both the Host and Card side have a 400 $\Omega$  pull down resistor. The 400 $\Omega$  resistor is used for discharge at power off and the 100k $\Omega$  resister is used for keep RST\_SIM/CLK\_SIM low when V<sub>CCB</sub> below V<sub>TH</sub>.

### EMI filter

All input/output driver stages are equipped with EMI filters to reduce interferences towards sensitive mobile communication.

### ESD protection

The device has robust ESD protections on all SIM card pins as well as on the  $V_{CCB}$  pin. The architecture prevents any stress for the host: the voltage translator discharges any stress to supply ground.

## Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter	Conditions		Min.	Max.	Unit
V <sub>CCA</sub>	Host supply voltage			GND - 0.5	2.4	V

Note1: Typical values measured at 25 °C

*Note2:* The voltage must not exceed 1.98 V steady state.

**Note3:** Skew between any two outputs of the same package switching in the same direction with same  $C_L$ .

 $\textit{\textit{Note4:}}\ V_{IL},\ V_{IH}$  depend on the individual supply voltage per interface

*Note5:* Guaranteed by design Note: This parameter is guaranteed by design and characterization.

## **Timing Waveform**

Note: This electric circuit only supplies for reference.

## **Application Circuits**

### Input/output capacitor considerations

It is recommended that a 1µF and 100nF capacitors having low Equivalent Series Resistance (ESR) are used respectively at V<sub>CCA</sub> and V<sub>CCB</sub> input terminals of the device. X5R and X7R type multi-layer ceramic capacitors (MLCC) are preferred because they have minimal variation in value and ESR over temperature. The maximum ESR should be <  $500m\Omega$  ( $50m\Omega$  typical).

### Layout consideration

The capacitors should be placed directly at the terminals and ground plane. It is recommended to design the PCB so that the  $V_{CCA}$  and  $V_{CCB}$  pins are bypassed with a capacitor with each ground returning to a common node at the GND pin of the device such that ground loops are minimized.

### Level translator stage

The architecture of the device I/O channel is shown in Figure 6. The device does not require an extra input signal to control the direction of data flow from host to SIM or from SIM to host.

As a change of driving direction is just possible when both sides are in HIGH state, the control logic is recognizing the first falling edge granting it control about the other signal side.

During a rising edge signal, the non-driving output is driven by a one- shot circuit to accelerate the rising edge. In case of a communication error or some other unforeseen incident that would drive both connected sides to be drivers at the same time, the internal logic automatically prevents stuck-at situation, so both I/Os will return to HIGH level once released from being driven LOW.

The channels RST and CLK just contain single direction drivers without the holding mechanism of the I/O channel, as these are just driven from the host to the card side.
